

IMPORT DATA USING TRANSFORM MAPS (SPREADSHEET)

PHASE 3 – PROJECT DESIGN

3.1 Introduction

The project design phase translates the identified requirements into a practical ServiceNow structure. The design defines the source data, staging area, transformation layer, and final target table. It also establishes how the imported employee information will be organized and presented through reports and dashboards.

3.2 Overall Data Flow

The overall data flow defines how employee information moves through the system from the external spreadsheet to the final reporting layer.

Spreadsheet	Employee Import (Import Set Table)	Transform Map	Employee Test (Target Table)	Reports & Employee Analytics Dashboards
--------------------	---	----------------------	---	--

3.3 Source Data Design

The source spreadsheet is designed with a header row followed by employee records. Each row represents an individual employee, while the fields contain employee identity and organizational information.

3.4 Target Table Design

The Employee Test table is designed to store the transformed employee records. The following fields define the structure of the target table.

Target Field	Data Type	Role
Employee ID	String	Employee identifier
Employee Name	String	Employee name
Email	String	Employee email
Department	String	Department classification
Location	String	Location classification

3.5 Staging Table Design

The Employee Import table functions as a temporary staging area for incoming employee data. The data is first loaded into this table before the Transform Map transfers it to the Employee Test table. This separation allows the import and transformation stages to be managed independently.

3.6 Transform Design

The Transform Map connects the source fields in the Employee Import table with the corresponding target fields in the Employee Test table. Auto Map Matching Fields can be used initially, followed by Mapping Assist where additional field mapping is required.

3.7 Coalesce Design

Coalesce is included in the design to handle repeated imports and prevent unnecessary duplicate records. A field such as Employee ID can be used to determine whether an incoming row matches an existing employee record. When a matching identifier is found, the existing record can be updated instead of creating another record.

3.8 Report Design

The reporting design provides structured views of employee information based on department, location, and individual employee details.

Report	Chart / Type	Grouping / Columns
Employees by Department	Pie Chart	Group by Department; Count
Employees by Location	Bar Chart	Group by Location; Count
Employee List Report	List	Employee ID, Employee Name, Email, Department, Location

3.9 Dashboard Design

The dashboard is named Employee Analytics Dashboards. It serves as a centralized presentation area where the three reports can be viewed together, providing a structured visual representation of employee information.

3.10 Design Benefits

- Separates imported source data from the final employee records.
- Makes the transformation process traceable.
- Supports duplicate prevention through Coalesce.

- Provides structured reporting for employee information.
- Creates a centralized visual view for administrators and HR teams.
